

Patient Appointment Analysis - Overview

Overview

Patient No-Shows permeate medical practices, across specialties, locations, and practice models. No-shows consistently cause problems for medical practices. Therefore, medical practices track their No-Show rates to realize the impact that No-Shows have on both their internal processes and bottom-line revenue.

There are many reasons why patients fail to make their appointments. However, there are demographic similarities across patients who no-show more consistently than others. This project analyzes medical appointments for a seven-month period (November 2015 – June 2016). Over 110,000 appointments are included in the underlying dataset. Factors under considerations include age, gender, alcoholism, diabetes, handicap, hypertension, patient's location, scheduled appointment time, and whether the patient received an automated SMS appointment reminder.

Key Objectives

- Identify factors that are shared among patients who routinely no-show for appointments
- Determine the most important factor that contributes to whether a patient is a no-show for their scheduled appointment
- Provide suggestions to minimize the number of No-Shows

Patient No-Show Appointment Analysis - Results

Analysis Results

The following factors were shared most among patients who were routinely No-Shows:

- Key contributing factor to No-Shows: Early Morning appointments (i.e., before 9AM) – 1.91 times likely to be No-Shows
- Patients without medical ailments and challenges (e.g., diabetes, hypertension, alcoholism, etc.), excluding handicapped individuals, are more apt to miss appointments
- Patients between the ages of 5 – 27 are 1.46 times likely to be No-Shows
- Females tends to be No-Shows more often than males

Recommendations

- Strategically schedule appointments after 9AM – 3PM, when possible
- Schedule patients between the ages of 5-27 after 3PM

Additional Suggested Analysis

- Patient's distance from treatment facility
